1 Basics

1.1 Semilattice polymorphisms

Definition. A map $f: D^2 \rightarrow D$ is called *semilattice operation* if

```
• f(x,x) = x (idempotent)

• f(x,y) = f(y,x) (commutative)

• f(f(x,y),z) = f(x,f(y,z)) (associative)
```

Theorem. $P(H) \rightarrow H$ iff H is homomorphic equivalent to a graph with semilattice polymorphism.

Remark. T.f.a.e.:

- $P(H) \rightarrow H$
- *H* has tree duality
- H has totally symmetric polymorphism for all arities
- H is homomorphic eq. to a graph with a semilattice polymorphism

Non-example. All polymorphisms of K_3 are of the form $(x_1,...,x_n) \mapsto f(x_i)$ for some $i \in \{1,...,n\}, f \in S_3$.

1.2 Path-consistency

Algorithm $PC_H(G)$. For solving CSP(H), H finite digraph

```
Input: finite digraph G
Data structure: L(x,y) \subset V(H)^2 \forall (x,y) \in V(G)^2

DO \forall (x,y) \in V(G)^2:

IF (x,y) \in E(G) THEN L(x,y) := E(H) ELSE L(x,y) := V(H)^2
DO WHILE list changes
DO \forall (u,v) \in L(x,y):

IF \nexists w \in V(H) : (u,w) \in L(x,z) \land (w,v) \in L(z,y) THEN remove (u,v) from L(x,y)
IF L(x,y) = \emptyset reject
```

Observations:

- If $PC_H(G)$ rejects, then $G \rightarrow H$
- Running time is cubic in the size of the input
- If AC_H solves CSP (H), then PC_H does too, since we also have lists L(x, x)
- PC cannot solve CSP(K_3) since $K_4 \rightarrow K_3$ but PC cannot decide

1.3 Majority operations

Definition. Operation $f: G^3 \to G$ is called *majority* if $\forall x, y \in D: f(x, x, y) = f(x, y, x) = f(y, x, x) = x$.

Examples. • Let $f: (\vec{C_k})^3 \to \vec{C_k}$ be the majority satisfying f(x, y, z) = x if $|\{x, y, z\}| = 3$. • Let $f: (\vec{T_k})^3 \to \vec{T_k}$ be the median majority (always returns the middle element) $f(x, y, z) := \min\{\max(x, y), \max\{y, z\}, \max\{x, z\}\}$

Lemma. Let f be a k-ary polymorphism of H, G finite digraph, $x, y \in V(G)$, L(x, y) be the list of (x, y) at the end of $PC_H(G)$. Then L is preserved by f.

Proof. We show by induction over the execution of $PC_H(G)$, that $\forall x, y \in V(H)$ at all times, if $(u_1, v_1), ..., (u_k, v_k) \in L(x, y)$, then $(f(u_1, ..., u_k), f(v_1, ..., v_k)) \in L(x, y)$. If $(x, y) \notin E(G)$.

IB Obvious, since f is a polymorphism

IS Let $x, y, z \in V(G)$, $(u_1, v_1), ..., (u_k, v_k) \in L(x, y)$ be arbitrary. From last step: $\forall i \in \{1, ..., k\} \exists w_i : (u_i, w_i) \in L(x, z) \land (w_i, v_i) \in L(z, y)$. By induction assumption, $(f(u_1, ..., u_k), f(w_1, ..., w_k)) \in L(x, z) \land (f(w_1, ..., w_k), f(v_1, ..., v_k)) \in L(z, y)$. Hence, $(f(u_1, ..., u_k), f(v_1, ..., v_k))$ will not be removed from L(x, y).

Theorem. PC_H solves CSP(H) if H has a majority polymorphism.

Proof. Let $f: H^3 \to H$ be a majority polymorphism and G instance of CSP (H). Suppose $L(x,y) \neq \emptyset \forall (x,y) \in V(G)^2$ when $PC_H(G)$ terminates. To show: $\exists h: G \to H$. We show by induction on i that every $h: G' \to H$ homomorphism from G' induced subgraph of G on i vertices which preserves L(x,y) can be extended to any other vertex of G.

IB Let $x_1, x_2, x_3 \in G$ be arbitrary and $h : \{x_1, x_2\} \to H$ homomorphism s.t. $(h(x_1), h(x_2)) \in L(x_1, x_2)$. It can be extended to x_3 s.t. $(h(x_1), h(x_3)) \in L(x_1, x_3)$ and $(h(x_3), h(x_2)) \in L(x_3, x_2)$, ow. $PC_H(G)$ would have removed $(h(x_1), h(x_2))$ from $L(x_1, x_2)$.

IS Let $h': G' \to H$ be a homomorphism that preserves lists, $x \in G \setminus G'$. Let $x_1, x_2, x_3 \in G'$, $h'_j := h|_{G' \setminus \{x_j\}}$. By induction assumption, h'_j can be extended to x s.t. the resulting homomorphism h_j preserves the lists. We show that the extension h of h' which maps x to $f(h_1(x), h_2(x), h_3(x))$ is a homomorphism that preserves the lists. To show: wlog $\forall y \in V(G')$: $(h(x), h(y)) \in L(x, y)$.

If $y \notin \{x_1, x_2, x_3\}$, then

$$h(y) = h'(y) = f(h'(y), h'(y), h'(y)) = f(h_1(y), h_2(y), h_3(y)).$$

Since $(h_i(x), h_i(y)) \in L(x, y) \forall i$ and f preserves L(x, y) by the last lemma, we have $(h(x), h(y)) \in L(x, y)$.

If $y \in \{x_1, x_2, x_3\}$, then wlog suppose $y = x_1$. Then $\exists v \in H \text{ s.t. } (h_1(x), v) \in L(x, y)$, ow. $PC_H(G)$ would have removed $(h_1(x), h_1(x_2))$. We have

$$h(y) = h'(y) = f(v, h'(y), h'(y)) = f(v, h_2(y), h_3(y)).$$

Since $(h_1(x), v), (h_2(x), h_2(y)), (h_3(x), h_3(y)) \in L(x, y)$, the lemma above implies $(h(x), h(y)) \in L(x, y)$.

1.4 Relational Structures

- More general than digraphs.
- New phenomena: e.g. exist structures with Maltsev polymorphisms but no majority polymorphisms.
- Arise naturally even if we are only interested in digraphs.

Example. "Precoloured" H-Colouring. Input: finite digraph G, partial map $p:V(G) \to V(H)$. Question: does p have an extension to a homomorphism from G to H? Future observation: it is easy to adapt arc/path-consistency algorithms to precoloured H-colouring.

Definition. Let the *signature* $\tau = \{R_1, R_2, ...\}$ be a set of symbols R_i of arrity $k_i \in \mathbb{N}$. A *relational* τ -*structure* \underline{A} consists of a domain A and a relation $R_i^{\underline{A}} \subseteq A^{k_i}$ for each relational symbol $R_i \in \tau$ of arrity k_i .

Definition. Let A, B be τ -structures, $h: A \to B$ is called a homomorphism if for all $R \in \tau$:

$$(a_1,...,a_k)\!\in\!R^{\underline{A}}\Longrightarrow (h(a_1),...,h(a_k))\!\in\!R^{\underline{B}}.$$

A homomorphism from \underline{A} to \underline{A} is called an *Endomorphism*. An injective endomorphism which also preserves complements of all relations is called *embedding*.

Definition. Let \underline{A} be a τ -structure. Then $CSP(\underline{A}) = \{\underline{B} \mid \underline{B} \text{ finite } \tau\text{-structure s.t. } \underline{B} \to \underline{A}\}.$

Example. $H = (\{v_1, ..., v_n\}, E)$. Precolored problem: $CSP((\{v_1, ..., v_n\}; E, \{v_1\}, ..., \{v_n\}))$. Concrete example:

We consider $(\{a, b, c, d\}; \{\{a, b\}, ...\}, \{d\}, \emptyset, \{b\})$ as input to CSP (\underline{A}) .

1.5 Primitive Positive Formulas

Definition. A τ -formula is a formula $\phi(x_1,...,x_n)$ of the form $\exists x_{n+1},...,x_l(\psi_1 \land ... \land \psi_m)$, where ψ_i are *atomic*, i.e. of the form

- $R(y_1,...,y_k), R \in T$ of arrity $k, y_1,..., y_k \in \{x_1,...,x_l\}$
- y = y' for $y, y' \in \{x_1, ..., x_l\}$
- \perp for the constant *false*.

Example. $\tau = \{E\}, \phi(x, y) := \exists u_1, u_2 E(x, u_1) \land E(u_1, u_2) \land E(u_2, y)$. Then $(V, E) \models \varphi(a, b)$ iff there is a path from a to b in (V, E) of length 3. For ex. $C_5 \models \varphi(a, b)$ iff $a \neq b$.

Definition. Let \underline{B} be a structure with finite relational signature. Then $\mathrm{CSP}(\underline{B})$ is the computational problem of deciding whether a given p.p. τ -sentence ϕ is true in \underline{B} . The p.p. τ -sentence ϕ is called an *instance* of $\mathrm{CSP}(B)$.

2 Logic

2.1 From Structures to Formulas

Definition. To a finite τ -structure \underline{A} , we can associate a unique p.p. τ -formula called the *canonical conjunctive query* $\phi(\underline{A})$. Variables are the elements of \underline{A} , all existentially quantified (such formulas without free variables are called *sentences*), conjuncts $R(a_1,...,a_k)$ for $R \in \tau$, k-ary s.t. $(a_1,...,a_k) \in R^{\underline{A}}$.

Example. $\phi(K_3) = \exists u \exists v \exists w : E(u, v) \land E(v, u) \land E(v, w) \land E(w, v) \land E(u, w) \land E(w, u).$

Proposition. A finite τ -structure, B a τ -structure. Then $A \to B$ iff $B \models \phi(\underline{A})$.

2.2 From Formulas to Structures

Definition. Let ϕ be a p.p.-formula, w.l.o.g. without =, \bot . Define the canonical structure $\underline{S}(\phi)$ as the τ -structure with domain consisting of all variables of ϕ and relations given by $(a_1,...,a_k) \in R^{\underline{S}(\phi)}$ iff $R(a_1,...,a_k)$ is conjunct in ϕ .

Proposition. Let \underline{B} be a τ -structure, ϕ p.p.- τ -sentence other than \bot . Then $\underline{B} \models \phi$ iff $\underline{S}(\phi) \rightarrow \underline{B}$.

2.3 Primitive Positive Definability

Definition. If \underline{A} a τ -structure, $\phi(x_1,...,x_k)$ a τ -formula. Then

$$\phi^{\underline{A}} := \{(a_1, ..., a_k) \mid A \models \phi(a_1, ..., a_k)\}$$

is the relation defined by ϕ over A.

Lemma. \underline{A} , \underline{B} relational structures s.t. A = B. Suppose all relations of \underline{A} are p.p.-definable in B. Then there is a polynomial-time reduction from CSP(A) to CSP(B).

In particular:

- $CSP(B) \in P \implies CSP(A) \in P$.
- CSP(A) NP-hard $\Longrightarrow CSP(B)$ is NP-hard.

Proof. Let τ, σ be the signatures of A, B respectively, ϕ a τ -sentence.

- 1. Replace each conjunct $R(y_1, ..., y_k)$ in ϕ by $\psi(y_1, ..., y_k)$, where ψ is the p.p.-definition of R over \underline{B} .
- 2. For each conjunct of the form y = y', remove y' from the quantifier prefix and replace all occurrences of y' by y.
- 3. Rewrite formula to a p.p.-sentence by pulling out all quantifiers. Resulting formula: ϕ' .

Claim 1. $A \models \phi \iff B \models \phi'$.

Claim 2. ϕ' can be computed in linear time from ϕ .

Corollary. $CSP(C_5)$ is NP-hard.

Proof. CSP(K_5) is NP-hard. E^{K_5} is p.p. definable in C_5 . Claim follows by the lemma above.

2.4 Cores

Definition. A structure <u>A</u> is called a *core* iff all its endomorphism are embeddings.

Proposition. For finite structure A, t.f.a.e.:

- 1. A is a core
- 2. All endomorphisms of \underline{A} are injective.
- 3. All endomorphisms of \underline{A} are surjective.
- 4. All endomorphisms of \underline{A} are automorphisms.

Remark. None of these are necessarily equivalent for infinite \underline{A} . Counterexamples:

- (N;<) and a map which moves everything except 0 by one to the left for $2 \iff 1$.
- $(\mathbb{Z}; 2\mathbb{Z})$ and $x \mapsto 2x$ for $3 \iff 1$.
- $(\mathbb{Z}; \{(x, x+1) \mid x \in \mathbb{Z}\}, \{(x, x+2) \mid x \in \mathbb{N}\} \text{ and } x \mapsto x + c \text{ for } 2, 3 \iff 4.$

Theorem. Every finite relational structure \underline{B} is homomorphically equivalent to a core, the core C is unique up to isomorphisms.

Proof. For existence, pick a $e \in End(\underline{B})$ of minimal range. Then the substructure of \underline{B} induced by e(B) is a core, homomorphically equivalent to \underline{B} via inclusion. For uniqueness, let \underline{C}_1 , \underline{C}_2 be cores of \underline{B} . Let $e_i: B \to C_i$ and $f_1:=e_1|_{V(C_2)}$, $f_2:=e_2|_{V(C_1)}$. Claim is that \underline{C}_2 and \underline{C}_1 are isomorph via f_1 . Suppose there exist $x,y\in V(C_2)$ s.t. $f_1(x)=f_2(y)$. Then $f_2\circ f_1$ is not injective. This contradicts \underline{C}_2 being a core since $f_2\circ f_1\in End(\underline{C}_2)$. Similarly: f_2 is injective, C_1 , C_2 both finite, hence $|C_1|=|C_2|$. Furthermore, $\exists n\in \mathbb{N}$ s.t. $(f_2\circ f_1)^n=\mathrm{id}$, thus $(f_1)^{-1}=(f_2\circ f_1)^{n-1}\circ f_2$ is a homomorphism.

2.5 Orbits

Proposition. In a finite core \underline{C} , all orbits are p.p. definable.

Proof. Let $C = \{c_1, ..., c_n\}$. Let $\psi_{c_1}(c_1)$ be the canonical conjunctive query except for the variable c_1 not being existentially quantified. Obviously, $\underline{C} \models \psi_{c_1}(c_1) \Longrightarrow \forall \alpha \in \operatorname{Aut}(\underline{C})$ is $\underline{C} \models \psi_{c_1}(\alpha(c_1))$. Suppose that $c_1' \in C$ s.t. $\underline{C} \models \psi_{c_1}(c_1')$. Let $c_2', ..., c_n' \in C$ be witnesses showing that $\underline{C} \models \psi_{c_1}(c_1')$. Then the map $c_i \mapsto c_{i'}$ is an endomorphism of \underline{C} , and also an automorphism since \underline{C} is a finite core. Hence ψ_{c_1} defines orbit of c_1 in $\operatorname{Aut}(\underline{C})$.

Proposition. If \underline{A} is a finite core, then $CSP(\underline{A})$ and $CSP(\underline{A}, \{a_1\}, ..., \{a_n\})$ are linear-time equivalent.

Proof. Let $\tau, \tau' = \tau \cup \{R_{a_1}, ..., R_{a_n}\}$ be the signatures of \underline{A} , $(\underline{A}, \{a_1\}, ..., \{a_n\})$, respectively. Let ϕ be a p.p τ' -sentence. If $R_{a_i}(x_1), ..., R_{a_i}(x_k)$ are conjuncts of ϕ , replace all occurences of $x_2, ..., x_k$ by x_1 in ϕ . Next, replace $R_{a_i}(x)$ by $\psi_{a_i}(x)$, where ψ_{a_i} is p.p definition of orbit of a_i over \underline{A} . Rewrite the resulting formula to a p.p τ -sentence ψ . Now $\underline{A} \models \psi$ iff $(\underline{A}, \{a_1\}, ..., \{a_n\}) \models \phi$.

2.6 Polymorphisms and p.p. definability

Which relations R are p.p. definable in A?

Lemma. Let \underline{A} be a structure and $R \subseteq A^k$ s.t. R is p.p. definable in \underline{A} . Then R is preserved by all polymorphisms of \underline{A} .

Proof. Suppose that $\psi(x_1,...,x_k)$ is a p.p. definition of R. Let $f \in \operatorname{Pol}(\underline{A})$ be n-ary. Let $t_1,...,t_n \in R$. We have to show $f(t_1,...,t_n) \in R$. We know: $\underline{A} \models \psi(t_i)$. Let $x_{k+1},...,x_l$ be existentially quantified variables of ψ . Let s_i be the extension of t_i that satisfies the quantifier-free part ψ' of ψ . Then since f is a polymorphism:

$$\underline{A} \models \psi'(f(s_1(1), ..., s_n(1)), ..., f(s_1(l), ..., s_n(l))).$$

Hence
$$\underline{A} \models \psi(f(s_1(1), ..., s_n(1)), ..., f(s_1(k), ..., s_n(k))).$$

Theorem (Geiger '68, Boduszuk, Kalužnin, Kotov, Romov '69). Let \underline{A} be a finite structure. Then R is p.p. definable in A iff R is preserved by all polymorphisms of A.

Proof. If $R \subseteq A^k$ is preserved by $\operatorname{Pol}(\underline{A})$, then also by $\operatorname{Aut}(\underline{A})$. W.l.o.g. $R = O_1 \cup ... \cup O_{\omega}$, where O_i is an orbit of k-tuples of \underline{A} . Since \underline{A} is finite, $\omega \in \mathbb{N}$. If $\omega = 0$, \bot is a p.p. definition of $R = \emptyset$. For each $j \leq \omega$, fix a representative $a_j \in O_j$. Let $b_1, b_2, ..., b_m$ be an enumeration of A^{ω} s.t. $b_i = (a_1(i), ..., a_{\omega}(i))$ for all $i \in \{1, ..., k\}$. Let $\{q_1, ..., q_l\} := A^{\omega} \setminus \{b_1, ..., b_k\}$. Claim is that $\psi(b_1, ..., b_k) := \exists q_1, ..., q_l \phi(\underline{A}^{\omega})$ is a p.p. definition of R. By assumption all homomorphisms from \underline{A}^{ω} to \underline{A} preserve R. Therefore, they map $b_1, ..., b_k$ to tuple in R, so every tuple $(b'_1, ..., b'_k) \in A^k$ that satisfies ψ (represents a homomorphism $A^{\omega} \to A$, $b_i \mapsto b'_i$) is in R, since $a_i = (b_1(i), ..., b_k(i)) \in R \ \forall i$. Conversely, let $t \in R$, then $t \in O_j$ for some $j \leq \omega \Longrightarrow$ there is $\alpha \in \operatorname{Aut}(\underline{A})$ s.t. $\alpha(a_j) = t$. The map $f(x_1, ..., x_{\omega}) := \alpha(x_j)$ is homomorphism $A^{\omega} \to A$, which shows that $A \models \psi(t_1, ..., t_k)$.

2.7 P.p. Interpretations and the CSP

Definition. A relational σ -structure \underline{B} has a *primitive positive interpretation* I in a τ -structure A if $\exists d \in \mathbb{N}$, called the *dimension* of I, and

- 1. a p.p. τ -formula $\delta_I(x_1,...,x_d)$ called the *domain formula*,
- 2. for each atomic σ -formula $\phi(y_1,...,y_k)$ a primitive positive τ -formula $\phi_I(\underline{x}_1,...,\underline{x}_k)$ (\underline{x}_i d-tuples),

 $\underline{A} \models \phi_I(\underline{a}_1, ..., \underline{a}_k).$

3. a surjective *coordinate map h* : $\{(a_1,...,a_d) \in A^d \mid \underline{A} \models \delta_I(a_1,...,a_d)\} \rightarrow B$, such that for all atomic σ -formulas ϕ and all tuples $\underline{a}_i \in D_h$, $\underline{B} \models \phi(h(\underline{a}_1),...,h(\underline{a}_k))$ iff

Lemma. Let \underline{A} be p.p. interpretable in \underline{B} . Then there is a polynomial-time reduction from $CSP(\underline{A})$ to $CSP(\underline{B})$.

Remark. Primitive positive interpretations can be composed: if \underline{C}_1 has a d_1 -dimensional p.p. interpretation I_1 in \underline{C}_2 , and \underline{C}_2 has an d_2 -dimensional p.p. interpretation I_2 in \underline{C}_3 , then \underline{C}_1 has a natural $(d_1 \cdot d_2)$ -dimensional p.p. interpretation in \underline{C}_3 , which we denote by $I_1 \circ I_2$. The coordinate map of $I_1 \circ I_2$ is defined by

$$(a_1^1,...,a_{d_2}^1,...,a_1^{d_1},...,a_{d_2}^{d_2}) \mapsto h_1(h_2(a_1^1,...,a_{d_2}^1),...,h_2(a_1^{d_1},...,a_{d_2}^{d_2})).$$

Theorem (Hell-Nešetřil '90). Let H be a finite undirected graph. Then either

- 1. H is bipartite (then $CSP(H) \in P$) or
- 2. H interprets every finite structure primitively positively, up to homomorphic equivalence (then $CSP(H) \in NP$ -complete).

Definition. Let C be a class of finite structures.

- 1. H(C) is the class of all finite structures which are homomorphic equivalent to some structure from C.
- 2. $C(\mathcal{C})$ is the class of all structures obtained by expanding a core structure in \mathcal{C} by singleton relations $\{a\}$.
- 3. PP(C) is the class of all finite structures which interpretable in some structure from C.

Let \mathcal{D} be the smallest class containing \mathcal{C} which is closed under H, C, PP.

Lemma. All idempotent polymorphisms of K_3 are projections.

Consequence. $R \subseteq (V(K_3))^k$ preserved by S_3 . Then R is p.p. definable in K_3 .

Proof. Let $f \in \operatorname{Pol}(K_3)$. Then $\hat{f}(x) := f(x,...,x)$ is a endomorphism of K_3 . This implies $\hat{f} \in S_3$ since K_3 is a finite core. The map $g(x_1,...,x_k) := (\hat{f})^{-1}(f(x_1,...,x_n))$ is an idempotent polymorphism of K_3 , thus a projection onto x_i for some $i \leq n$ by the lemma above, which means $f(x_1,...,x_n) = \hat{f}(x_i)$. Thus f preserves R. Hence, R is p.p. definable.

Theorem. $PP(K_3)$ contains all finite structures.

Lemma. $C(\mathcal{C}) \subseteq H(PP(\mathcal{C}))$.

Proof. Let $\underline{B} \in \mathcal{C}$ be a core, $c \in B$, $\underline{C} := (\underline{B}, \{c\})$. The orbit O of c is p.p. definable in \underline{B} . We give a 2-dimensional p.p. interpretation of a structure \underline{A} with the same signature $\tau \cup \{R_c\}$ as \underline{C} . Let $R_c^{\underline{A}} := \{(a, a) \mid a \in O\}$ and for $R \in \tau$ and the arity of R is k then define

$$R^{\underline{A}} := \{((a_1, b_1), ..., (a_k, b_k)) \in (A^2)^k \mid (a_1, ..., a_k) \in R^{\underline{B}} \land b_1 = ... = b_k \in O\}.$$

Then *A* is homomorphic equivalent to $C = (B, \{c\})$:

- 1. $a \mapsto (a, c)$ is a homomorphism from \underline{C} to \underline{A}
 - $(a_1,...,a_k) \in R^{\underline{C}}$ for $R \in \tau \implies ((a_1,c),...,(a_k,c)) \in R^{\underline{A}}$. $R_{\underline{C}}^{\underline{C}} = \{c\}$ is preserved since $(c,c) \in R_{\underline{C}}^{\underline{A}}$.
- 2. We will define a homomorphism h from A to C. For every $a \in O$, fix $\alpha_a \in Aut(B)$ s.t. $\alpha_a(a) = c$. Define $h(a, b) := \alpha_b(a)$ if $b \in O$, otherwise arbitrarily.
 - $R \in \tau$ k-ary, $t = ((a_1, b_1), ..., (a_k, b_k)) \in R^{\underline{A}}$. Then $b_1 = ... = b_k =: b \in O$ and we have that $h(t) = (\alpha_b(a_1), ..., \alpha_b(a_k)) \in R^{\underline{C}}$ since α_b preserves $R^{\underline{B}}$. For $(a, a) \in R^{\underline{A}}$, we have $h(a,a) = \alpha_a(a) = c \in R_c^{\underline{C}}$.

Theorem. $\mathcal{D} = H(PP(\mathcal{C})).$

Proof. It is enough to show that $H(PP(\mathcal{C}))$ is closed under H, C, PP.

Definition. A clique where one edge is missing is called a *diamond*. A graph is called diamond-free if it does not contain a copy of a diamond.

Lemma. Let G be a finite, non-bipartite graph. Then H(PP(G)) contains a diamond-free core with a K_3 .

Proof. We may assume:

- 1. $G' \in H(PP(G))$ not bipartite $\Longrightarrow |G'| \ge |G|$, otherwise replace G with G'.
- 2. G contains a K_3 . If not, let k be the length of the shortest cycle in G, $E(G)^{k-2}$ is p.p. definable in G and $G' := (V(G), E(G)^{k-2})$ contains a triangle.
- 3. Every vertex of G lies in a K_3 . Otherwise, replace G by a subgraph defined by $\exists u, v(E(x, u) \land E(u, v) \land E(v, x).$

Claim 1. *G* does not contain K_4 . Otherwise, if $a \in V(G)$ lies in a K_4 . The subgraph G'induced by $\{x \in V(G) \mid E(x, a)\}$ is not bipartite (contains K_3) and strictly smaller than G. A contradiction to our first assumption.

Claim 2. *G* is diamond-free. To see this, let *R* be defined as follows:

$$R(x, y) : \iff \exists u, v (E(x, u) \land E(x, v) \land E(u, v) \land E(u, y) \land E(v, y))$$

and let T be the transitive closure of R. Then: T is reflexive (since every vertex lies in a triangle), obviously symmetric and transitive. Since G is finite, there exists $n \in \mathbb{N}$ s.t. $\exists u_1,...,u_n(R(x,u_1) \land R(u_1,u_2) \land ... \land R(u_n,y))$ defines T. The factor graph G/T is not bipartite since $T \cap E = \emptyset$. Otherwise, let $(a, b) \in T \cap E$. Choose (a, b) s.t. the shortest sequence $a = a_0, a_1, ..., a_n = b$ with $R(a_0, a_1) \land R(a_1, a_2) \land ... \land R(a_{n-1}, a_n)$ is the shortest possible. This sequence cannot be of the form $R(a_0, a_1)$ because G does not contain K_4 .

• Suppose n = 2k. Let u_i and v_i be the top and bottom vertices in the diamond $R(a_{i-1}, a_i)$. Let S be the set defined by

$$\exists x_1,...,x_k (E(u_{k+1},x_1) \land E(v_{k+1},x_1) \land R(x_1,x_2) \land ... R(x_{k-1},x_k) \land E(x_k,x)).$$

We observe that $a_0, u_1, v_1 \in S$ form a triangle. If $a_n \in S$ we obtain a contradiction to minimal choice of n. Hence the graph G' induced by p.p. definable set S is nonbipartite and |G'| < |G|. Contradiction to the first assumption.

• Suppose n = 2k + 1, we can argue analogously with S defined by

$$\exists x_1,...,x_k (E(u_{k+1},x_1) \land E(v_{k+1},x_1) \land R(x_1,x_2) \land ... R(x_{k-1},x_k))$$

and again obtain a contradiction.

Hence, G/T is not bipartite. This implies that T is the trivial equivalence relation, which implies that G does not contain any diamonds.

Lemma. Let G be diamond-free, $h:(K_3)^k \to G$ a homomorphism. Then: $h((K_3)^k) \cong (K_3)^m$ for some $m \leq k$.

Lemma. Let G be a finite graph with a K_3 subgraph, diamond-free, core. There is a $k \in \mathbb{N}$ s.t. $(K_3)^k \in PP(C(G))$.

Remark: This implies $K_3 \in H(PP(G))$ by the first lemma, since $H(PP(C(G))) \subseteq H(PP(G))$.

Proof of the first lemma. Let $I = \{i_1, ..., i_l\} \subseteq \{1, ..., k\}$, $pr_I : \{0, 1, 2\}^k \to \{0, 1, 2\}^l$ defined via $pr_I := (x_{i_1}, ..., x_{i_l})$. Let $h : (K_3)^k \to G$ be a homomorphism. Choose $I \subseteq \{1, ..., k\}$ maximal such that $\ker(h) \subseteq \ker(pr_I)$ (i.e. if two elements have the same image, their coordinates must coincide on I. Such an I exists, since we can always choose $I := \emptyset \Longrightarrow \ker(pr_\emptyset) = \{0, 1, 2\}^k$).

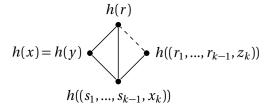

We need to prove: $\ker(h) = \ker(p r_I)$. For $j \notin I$ exist $x, y \in (K_3)^k$ such that h(x) = h(y) but $x_i \neq y_j$. To show: for all $z_1, ..., z_k, z_i' \in \{0, 1, 2\}$:

$$h(z_1,...,z_j,...z_k) = h(z_1,...,z_j',...,z_k),$$

i.e. if we two elements only differ on a coordinate outside of I, the images under h still coincide ($\ker(p\,r_I)\subseteq\ker(h)$). We can w.l.o.g. assume that $z_j\neq x_j,\,z_j'=x_j$, and j=k. Now, the proof goes as follows:

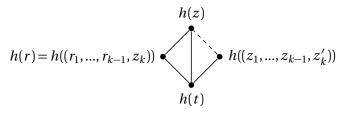

- From exercises, we know that every two vertices of $(K_3)^k$ have a common neighbour. Let r be a common neighbour of x and z, then it also is a neighbour of $(z_1, ..., z_{k-1}, z_k')$, since $z_k' = x_k$.
- For all $i \neq k$, choose $s_i \notin \{r_i, y_i\}$. Since $x_k \notin \{r_k, y_k\}$, $(s_1, ..., s_{k-1}, x_k)$ is a common neighbour of r and y.
- $(r_1, ..., r_{k-1}, z_k)$ is a common neighbour of x and $(s_1, ..., s_{k-1}, x_k)$.
- For all $i \neq k$, choose $t_i \notin \{z_i, r_i\}$, then choose $t_k \notin \{z_k, z_k'\}$. Then t is a common neighbour of z and $(z_1, ..., z_{k-1}, z_k')$ and $(r_1, ..., r_{k-1}, z_k)$.

From the relations above imply that $h(r) = h(r_1, ..., r_{k-1}, z_k)$ since otherwise we would get a diamond

2 LOGIC

But this also implies $h(z) = h(z_1, ..., z_{k-1}, z'_k)$ since otherwise we would get a diamond

Proof of the second lemma. Let G be diamond-free with K_3 subgraph. We will construct a sequence of subgraphs $G_1 \subsetneq G_2 \subsetneq ...$ of G s.t. $G_i \cong (K_3)^{k_i}$, $k_i \in \mathbb{N}$. Let G_1 be the K_3 copy in G. Induction on i: Suppose G_i has already been defined. If $G_i \cong (K_3)^{k_i}$ is p.p definable in G, then we are done. Otherwise $\exists f \in \operatorname{Pol}(G)$ idempotent (since it preserves the singleton relations) s.t. $f(v_1,...,v_n) \notin V(G_i)$ for $v_1,...,v_k \in V(G_i)$, then $G_i \lneq f(G_i^k) =: G_{i+1}$ and $G_{i+1} \cong (K_3)^{k_{i+1}}$ for some k_{i+1} by the previous lemma. Since this chain is strictly increasing and G finite, the claim follows.

3 Universal algebra

Definition. • A τ -structure A s.t. τ only consists of functional symbols is called algebra.

- τ -terms are words of the form f $t_1 \cdots t_n$, where $f \in \tau$, n-ary and $t_1, ..., t_n$ are τ -terms, the variables $x_1, ...$ are always τ -terms.
- a term operation is an evaluation map $(t x_1 \cdots x_n)^{\underline{A}} : A^n \to A, (a_1, ..., a_n) \mapsto t(a_1, ..., a_n)$
- Let $Clo(\underline{A})$ be the set of all term operations of \underline{A} , it contains all projections $(x_i)^{\underline{A}}$ and is closed under compositions. Hence it is a clone.
- Let \underline{S} be a relational structure. An algebra \underline{A} with s.t. $Clo(\underline{A}) = Pol(\underline{S})$ is called a *polymorphism algebra* of \underline{S} .

3.1 Operations on algebras

Definition. Let \mathcal{C} be a class of τ -algebras.

- 1. $H(\mathcal{C})$ is the class of all homomorphic images of $A \in \mathcal{C}$.
- 2. $S(\mathcal{C})$ is the class of all subalgebras of $A \in \mathcal{C}$.
- 3. $P(\mathcal{C})$ is the class of all products of algebras from \mathcal{C} .
- 4. $P_{\text{fin}}(\mathcal{C})$ is the class of all finite products of algebras from \mathcal{C} .

A class of τ -algebras $\mathcal V$ is called a *variety* resp. *pseudovariety* if it is closed under H, S, P resp. H, S, P_{fin} . Let $\mathcal V(\mathcal C)$ resp. $\mathcal V_{\mathrm{fin}}(\mathcal C)$ denote the smallest variety resp. pseudovariety which contains $\mathcal C$.

Proposition.
$$V(C) = HSP(C), V_{fin}(C) = HSP_{fin}(C)$$

Lemma. Let $\underline{A}, \underline{B}$ be polymorphism algebras of $\underline{S}, \underline{T}$. Then $\underline{A} \in HSP(\underline{B})$ iff $\underline{S} \in PP(\underline{T})$.

Proof. We only show the first implication. There $\exists \underline{C} \leq \underline{B}^d$ and $h : \underline{C} \to \underline{A}$. Construction of a p.p. interpretation of \underline{S} in \underline{T} :

- All operations of \underline{B} preserve \underline{C} (seen as d-ary relation). By the BKKR Theorem, \underline{C} has a p.p. definition $\psi(x_1,...,x_d)$ =: $\delta_I(x_1,...,x_d)$ in \underline{B} .
- Choose h as the coordinate map. Let $f^{\underline{A}}$ be a operation of \underline{A} , $R^{\underline{S}}$ a relation of S. Then $R^{\underline{S}}$ is preserved by $f^{\underline{A}}$ which implies that $f^{\underline{B}}$ preserves $h^{-1}(R^{\underline{A}})$. Hence, polymorphisms of \underline{T} preserve $h^{-1}(R^{\underline{S}})$, which yields $\phi(x_1,...,x_n)=:R(x_1,...,x_n)$, a p.p. definition of it in T.
- ker h is a congruence of \underline{C} , hence it is, seen as a 2d-ary relation over \underline{B} preserved by all operations of \underline{B} . By BKKR, it has a p.p. definition in \underline{T} . This definition becomes the formula $=_I$

Corollary. Let \underline{B} be a polymorphism algebra of \underline{T} , $\underline{A} \in HSP_{fin}(\underline{B})$ s.t. |A| = 3 and all operations are unary, then $K_3 \in PP(\underline{T})$.

Identities

Let τ be a functional signature. A τ -sentence is called *universal conjunctive* if it is of the form $\forall x_1, ..., x_n : \psi_1(\cdot) \land ... \land \psi_m(\cdot)$, where $\psi_1, ..., \psi_m$ are atomic.

Example. • Semilattice operation:

$$\forall x, y, z : f(x, y) = f(y, x) \land f(f(x, y), z) = f(x, f(y, z)) \land f(x, x) = x.$$

- Majority operation.
- Maltsev operation.

Theorem (Birkhoff). Let $\underline{A}, \underline{B}$ be finite τ -algebras. TFAE:

- (1) $\underline{A} \in HSP_{fin}(\underline{B})$.
- (2) $A \in HSP(B)$.
- (3) All universal conjunctive sentences, which are true in B, are true in A.

Consequence: $K_3 \notin PP(\underline{T})$, \underline{B} polymorphism algebra of \underline{T} . By the previous lemma, $HSP_{fin}(\underline{B})$ contains no polymorphism algebras \underline{A} of K_3 . Then \exists universal conjunctive sentence ϕ which is true in \underline{B} but not in \underline{A} .

Abstract clones

Definition. An (*abstract*) *clone* is a structure $\underline{C} = (C^{(0)}, C^{(1)}, ...; (\pi_i^k)_{1 \le i \le k}, (comp_i^k)_{k,l \ge 1})$

- $C^{(k)}$ are called the k-ary operations of \underline{C}
- π_i^k are constants in C^(k) (the *projections*)
 comp_l^k: C^(k) × (C^(l))^k → C^(l) is a operation of arity k + 1

s.t.

$$\begin{aligned} comp_k^k(f,\pi_1^k,...,\pi_k^k) &= f\\ comp_l^k(\pi_i^k,f_1,...,f_k) &= f_i\\ comp_l^k(f,comp_l^m(g_1,h_1,...,h_m),...,comp_l^m(g_k,h_1,...,h_m)) &=\\ comp_l^m(comp_m^k(f,g_1,...,g_k),h_1,...,h_m). \end{aligned}$$

Clone homomorphisms

Definition. C, D clones, $\mu: C \to D$ clone homomorphism if

- $\mu(C^i) \subseteq D^{(i)}$
- $\mu((\pi_i^k)^{\underline{C}}) = (\pi_i^k)^{\underline{D}}, i \leq k$
- $\mu(comp(f,g_1,...,g_n)) = comp(\mu(f),\mu(g_1),...,\mu(g_n)), f \in C^{(n)}, g_1,...,g_n \in C^{(m)}.$

Example. • Every clone has a homomorphism into the clone of all functions on an singleton.

• All algebras \underline{A} s.t. $|A| \ge 2$, where all operations are projections, have isomorphic clones. These are denoted with $\underline{\text{Proj}}$. For ex. $\underline{\text{Proj}} = \text{Pol}(\{0,1,2\}; \ne, \{0\}, \{1\}, \{2\}) = \text{Pol}(\{0,1\}; \{(0,0,1), (0,1,0), (1,0,0)\})$.

Addition to the Birkhoff's Theorem:

Theorem (Birkhoff). Let $\underline{A}, \underline{B}$ be finite τ -algebras. TFAE:

- (1) $\underline{A} \in HSP_{fin}(\underline{B})$.
- (2) $A \in HSP(B)$.
- (3) All universal conjunctive sentences, which are true in \underline{B} , are true in \underline{A} .
- (4) $\mu: Clo(\underline{B}) \to Clo(\underline{A}), \mu(t^{\underline{B}}) := t^{\underline{A}}$ is a well defined surjective clone homomorphism.

Proof.
$$\mu$$
 is well defined \iff $(t^{\underline{B}} = s^{\underline{B}} \implies t^{\underline{A}} = s^{\underline{A}}) \iff$ (3).

Consequence. *S finite structure. TFAE:*

- (1) \forall finite structures $T \exists : T \in PP(S)$
- (2) $K_3 = (\{0, 1, 2\}; \neq, \{0\}, \{1\}, \{2\}) \in PP(S)$
- (3) $Clo(\underline{B}) = Pol(\underline{S}) \Longrightarrow \exists \underline{A} \in HSP_{fin}(\underline{B}) \text{ s.t. } Clo(\underline{A}) = \underline{Proj}.$
- (4) $\exists \mu : \text{Pol}(\underline{S}) \rightarrow \underline{\text{Proj}} \ clone \ homomorphism.$

Question: Which clones don't have a clone homomorphism to Proj.

Lemma. \underline{C} clone, \underline{F} clone of finite algebra s.t. $\underline{C} \nrightarrow \underline{F} \Longrightarrow \exists p.p. \tau$ -sentence which is true in \underline{C} but not in \underline{F} (τ signature of abstract clones).

Proof. Let \underline{E} be expansion of \underline{C} by constants $c_e \forall e \in E$, $V := \{\psi \text{ atomic sentences } | \underline{E} \models \psi \}$, U := f.o. theory of \underline{F} . Suppose $\exists \underline{M} \models U \cup V$. Then the τ -reduct of restriction of \underline{M} to $\bigcup_i M^{(i)}$ is isomorphic to \underline{F} (since all f.o. sentences which completely describe \underline{F} have to be true in this reduct), we identify it with \underline{F} .

For all constants c_e , $c_e^{\underline{M}} \in \underline{F}$. Since \underline{M} satisfies all atomic formulas that hold in \underline{E} , we have that the $\mu : \underline{C} \to \underline{F}$, $e \mapsto c_e^{\underline{M}}$ is a clone homomorphism. Contradiction. So $U \cup V$ is unsatisfiable, then by compactness of first-order logic, $\exists V' \subseteq V$ finite s.t. $U \cup V'$ is unsatisfiable. Replace the constant symbols c_e in the sentences from V' with existentially quantified variables and let ψ be their conjunction. Then ψ is a p.p. sentence which is false in F.

3.5 Taylor terms

Definition. A *Taylor term* of a τ -algebra \underline{B} is a τ -term $t(x_1,...,x_n)$, $n \ge 2$ s.t. \exists variables $(z_{i,j}), (z'_{i,j}) \in \{x,y\}^{n \times n}$, $z_{i,i} \ne z'_{i,i} \forall i$ and $\underline{B} \models \forall x,y \bigwedge_{i=1}^n (t(z_{i,1},...,z_{i,n}) = t(z'_{i,1},...,z'_{i,n}))$.

Example. • Semilattice operation f(x, y) = f(y, x):

$$(z_{i,j}) := \begin{pmatrix} x & y \\ y & x \end{pmatrix}, \quad (z'_{i,j}) := \begin{pmatrix} y & x \\ x & y \end{pmatrix}$$

• Majority operation f(x, y, x) = f(x, x, y) = f(y, x, x) (= x):

$$(z_{i,j}) := \begin{pmatrix} x & x & y \\ x & y & x \\ x & x & y \end{pmatrix}, \quad (z'_{i,j}) := \begin{pmatrix} y & x & x \\ y & x & x \\ x & y & x \end{pmatrix}$$

• Maltsev operation f(x, x, y) = f(y, x, x) = f(y, y, y) (= y):

$$(z_{i,j}) := \left(\begin{array}{ccc} y & x & x \\ x & x & y \\ y & y & y \end{array}\right), \quad (z'_{i,j}) := \left(\begin{array}{ccc} x & x & y \\ y & y & y \\ y & x & x \end{array}\right)$$

Theorem (Taylor; Hobby & McKenzie, Chapter 9). Let \underline{B} be an idempotent Algebra (i.e. all its operations are idempotent). TFAE:

- (1) $Clo(B) \rightarrow Proj$
- (2) B has a Taylor term.

Lemma. Let $\underline{S} \in H(\underline{T})$. Then \underline{T} has a Taylor polymorphism $\Longrightarrow \underline{S}$ has a Taylor polymorphism.

Proof. Let $h: \underline{T} \to \underline{S}$, $g: \underline{S} \to \underline{T}$, $(x_1, ..., x_n) \mapsto t(x_1, ..., x_n)$ a Taylor polymorphism of $\underline{T} \Longrightarrow (x_1, ..., x_n) \mapsto h(t(g(x_1), ..., g(x_n)))$ is a polymorphism and $\forall 1 \le i \le n, (z_{i,j}), (z'_{i,j}) \in \{x, y\}^{n \times n}, z_{i,i} \ne z'_{i,i}$: $h(t(g(z_{1,i}), ..., g(z_{n,i}))) = h(t(g(z'_{1,i}), ..., g(z'_{n,i})))$.

Lemma. Let $\underline{S} \in PP(\underline{T})$. Then \underline{T} has a Taylor polymorphism $\Longrightarrow \underline{S}$ has a taylor polymorphism.

Proof. By Birkhoff's Theorem, all universal conjunctive sentences which hold in $Pol(\underline{T})$ also hold in $Pol(\underline{S})$, since $Pol(\underline{S}) \in HSP(Pol(\underline{T}))$ by the Lemma at the beginning of this chapter.

Lemma. Let $\underline{S} \in C(\underline{T})$. Then \underline{T} has a Taylor polymorphism $\Longrightarrow \underline{S}$ has a taylor polymorphism.

Proof. First proof: let t be a Taylor polymorphism of \underline{T} , wlog. \underline{T} core (ow. take a core of \underline{T}). The unary polymorphism $\hat{t}(x) := t(x,...,x)$ has an inverse $\hat{t}^{-1} \in \operatorname{Pol}(\underline{T})$. Then $\hat{t}^{-1}(t(x_1,...,x_n)) \in \operatorname{Pol}(\underline{S})$ is an indempotent Taylor polymorphism. Second proof: $C(\underline{T}) \subseteq H(PP(\underline{T}))$

Corollary. Let \underline{T} be a finite structure. Then t.f.a.e.:

- (1) $K_3 \notin H(PP(\underline{T}))$
- (2) T has a Taylor polymorphism.

Proof. (2) \Longrightarrow (1): Every structure $\underline{S} \in H(PP(\underline{T}))$ has a Taylor polymorphism. (1) \Longrightarrow (2): Let \underline{T}' be the core of \underline{T} , \underline{C} be the expansion of \underline{T}' with all constants, then $\underline{C} \in C(H(\underline{T})) \subseteq H(PP(\underline{T}))$. Thus $K_3 \notin PP(\underline{C})$, then $Pol(\underline{C}) \nrightarrow Proj$ by the consequence of Birkhoff's Theorem. Furthermore, $Pol(\underline{C})$ idempotent. Then, by the Taylor's Theorem, $Pol(\underline{C})$ contains a Taylor operation $\Longrightarrow \underline{T}'$ and \underline{T} have a Taylor polymorphism.

Corollary. If T has no Taylor polymorphism \implies CSP(T) is NP-hard.

Theorem (Tractability Conjecture, Bulatov 2017). *If* \underline{T} *has a Taylor polymorphism, then* $CSP(T) \in P$.

Warning Examples. • There are finite cores \underline{T} s.t. $K_3 \in PP(C(\underline{T})) \subseteq H(PP(\underline{T}))$ but $K_3 \notin PP(T)$.

• There are finite structures \underline{T} with impotent $\operatorname{Pol}(\underline{T})$ s.t. $PP(\underline{T}) \subsetneq H(PP(\underline{T}))$. I.e.: $\underline{T} := (\mathbb{Z}_2^2; R_{a,b})$ for $a, b \in \{0,1\}$, where

$$R_{a,b}^{\underline{T}} := \{(x, y, z) \in T^3 \mid x + y + z = (a, b).$$

Let \underline{T}' be a reduct of \underline{T} with signature $\tau = \{R_{0,1}, R_{0,0}\}$. Then $\underline{S} \in H(\underline{T}')$ for a certain structure \underline{S} with domain $S = \mathbb{Z}_2$. Furthermore $\underline{T}' \in PP(\underline{T}), \underline{S} \in H(PP(\underline{T})) \setminus PP(\underline{T})$.

Definition. Let *A* be an algebra, $s \in Clo(A)$ is called *Siggers* if

$$\forall x, y, z : s(x, y, x, z, y, z) = s(y, x, z, x, z, y).$$

Proposition. T has Siggers term iff T has Taylor term.

Proof. We only prove one direction since any Siggers term is a Taylor term. Let \underline{B} be a finite algebra with a Taylor term. Choose $k \in \mathbb{N}$, $a, b, c \in B^k$ s.t. $B^3 = \{(a_i, b_i, c_i) \mid i \leq k\}$. For $u, v \in B^k$, define $R(u, v) := \exists s \in \text{Clo}(\underline{B}) : u = s(a, b, a, c, b, c) \land v = s(b, a, c, a, c, b)$. Then

- R is symmetric: if R(u, v) via s, then R(v, u) via $s'(x_1, x_2, x_3, x_4, x_5, x_6) := s(x_2, x_1, x_4, x_3, x_6, x_5)$
- Nodes a, b, c induce a K_3 in the graph $G := (B^k, R)$ via projections.
- *R* is preserved by Clo(*B*).
- *G* has Taylor polymorphism.

If $\exists u \in G : R(u, u)$, then \underline{B} has Siggers. If not, then G is loopless, undirected, finite s.t. $K_3 \in H(PP(G))$. Contradiction to G having a Taylor polymorphism.

4 Functions and Relations

4.1 Pol-Inv

Let O_B be the clone of all operations on B, R_B be the set of all relations of finite arity on B. Let $F \subseteq O_B$, $\Phi \subseteq R_B$. Then

- $\operatorname{Inv}(F) := \{R \in R_B \mid \forall f \in F : f \text{ preserves } R\}.$
- $\operatorname{Pol}(\Phi) := \{ f \in O_B \mid \forall R \in \Phi : f \text{ preseves } R \}.$
- $\langle F \rangle$ is the smallest clone containing F.
- $\langle \Phi \rangle$ is the smallest set of relations containing Φ which is closed under p.p. definability.

Lemma. (1) InvPol
$$\Phi = \langle \Phi \rangle$$

(2) PolInv $F = \langle F \rangle$

Proof. Proof for (2): One inclusion is obvious. For the other: Let $f \in Pol \text{Inv } F$ be k-ary, $B^k = \{b_1, ..., b_n\}$, $R := \{(g(b_1), ..., g(b_n)) \mid g \in \langle F \rangle\}$. Then:

- $R \in \operatorname{Inv} F \Longrightarrow f$ preserves R.
- $(\pi_i^k(b_1), ..., \pi_i^k(b_n)) \in R$, since $\pi_i^k \in \langle F \rangle$

Previous points imply $(f(b_1),...,f(b_n)) \in R \implies (f(b_1),...,f(b_n)) = (g(b_1),...,g(b_n))$ for some $g \in \langle F \rangle$.

Definition. A map $f: B^k \to B$ depends on the argument i if $\exists r, s \in B^k$ s.t. $f(r) \neq f(s)$ but $\pi_i^k(r) = \pi_i^k(s) \forall j \in \{1, ..., n\} \setminus \{i\}$.

Lemma. Let $f: B^k \to B$. Then t.f.a.e.:

- (1) f is essentially unary, i.e. $\exists i \in \{1,...,k\}, \widetilde{f} : B \to B$ s.t. $f(x_1,...,x_n) = \widetilde{f}(x_i)$
- (2) f preserves $P_B^3 := \{(x, y, z) \in B^3 \mid x = y \lor y = z\}.$
- (3) f preserves $P_R^4 := \{(x, y, u, v) \mid x = y \lor u = v\}$
- (4) f depends only on one argument

Proof. Exercise.

Example. $Pol(K_n; \{1\}, ..., \{n\}) = \underline{Proj} = Pol(P_{\{1,...,n\}}^3, \{1\}, ..., \{n\}).$

4.2 Minimal clones

Definition. A clone $F \subseteq O_B$ is called

- trivial if $F \cong Proj$
- minimal if $\widetilde{F} \subset F$ a non-trivial clone $\Longrightarrow \widetilde{F} = F$.

An operation $f \in O_B$ is called *minimal* if $\langle f \rangle$ is minimal and f is of minimal arity (implies that every g generated by f is a projection or generates f).

Lemma. Every non-trivial clone F contains a minimal operation.

4 FUNCTIONS AND RELATIONS

Proof. Consider any strict decreasing chain of non-trivial clones $F \supset F_1 \supset F_2 \supset ...$. The set $\bigcup_{i \ge 1} \operatorname{Inv}(F_i)$ is closed under p.p. definability. Thus $F_i \supseteq \operatorname{Pol} \bigcup_{i \ge 1} \operatorname{Inv}(F_i)$ for all i. It also does not contain the relations $R_B^3, \{b_1\}, ..., \{b_n\}$, otherwise, these would be contained in some $\operatorname{Inv} F_i$, since the chain is strictly decreasing—contradiction to minimality. Hence, $\operatorname{Pol} \bigcup_{i \ge 1} \operatorname{Inv}(F_i)$ is a non-trivial lower bound of this chain. By Zorn's Lemma, this partial order contains a minimal element, which is generated by a minimal operation. \square

Definition. A map $f: B^k \to B$ is called a *semiprojection* if $f(x_1, ..., x_k) = x_i$ if $|\{x_1, ..., x_k\}| < k$.

Theorem (Rosenberg's 5 types). *Every minimal operation on a finite B is one of these:*

- (1) f is unary and f(f(x)) = x or f(f(x)) = f(x).
- (2) f is binary and f(x, x) = x.
- (3) f is Maltsev
- (4) f is majority
- (5) f is a semiprojection of arity less than |B|

Lemma (Swierczkowski). Let f be a k-ary operation s.t. the outcome of identifying of any two arguments is a projection. Then f is a semi-projection.

Proof of last Theorem. Nothing to prove if f is unary or binary. Let f be ternary. By minimality of f, $f_1(x, y) := f(y, x, x)$, $f_2(x, y) := f(x, y, x)$, $f_3(x, y) := f(x, x, y)$ are projections. We consider all 8 possible cases:

| $(f_1, f_2, f_3)(x, y)$ | resulting type |
|-------------------------|-------------------------------------|
| (x, x, x) | f is majority |
| (x, x, y) | f is 3rd semi-projection |
| (x, y, x) | f is 2nd semi-projection |
| (y, x, x) | f is 1st semi-projection |
| (y, x, y) | f is Maltsev |
| (x, y, y) | g(x, y, z) := f(y, x, z) is Maltsev |
| (y, y, x) | g(x, y, z) := f(x, z, y) is Maltsev |
| (y, y, y) | f is minority, thus Maltsev |

Let f be k-ary for $k \ge 4$. By minimality of f, the outcomes of identifying variables are projections. By the lemma of Swierczkowski, f is a semi-projection.

Theorem (Post '41). The minimal operations $f: \{0,1\}^k \rightarrow \{0,1\}$ are

- (1) The unary constant functions
- (2) The negation \neg
- (3) $(x, y) \mapsto \min\{x, y\}, (x, y) \mapsto \max\{x, y\}$
- (4) Minority
- (5) Majority

Proof. Trivial for f unary. If f is binary, $\hat{f}(x) := f(x, x) = x \implies f$ is idempotent \implies 4 possibilities, 2 of them are projections, 2 maximum and minimum. If f is k-ary for $k \ge 3$, then we get some of the Rosemberg's types and semi-projections on $\{0,1\}$ are projections.

Lemma. The minimal operations which are Maltsev, are minorities f(x, y, x) = y.

Proof. Suppose f(x, y, x) = x. Consider g(x, y, z) := f(x, f(x, y, z), z). Then we have g(x, x, y) = f(x, y, y) = x, g(x, y, x) = f(x, x, x) = x and g(y, x, x) = f(y, y, x) = x. Contradiction to f being minimal since g cannot generate f and is no projection. \Box

Theorem (Schaefer '78). Let \underline{B} be a relational structure with |B| = 2. Then either $Pol(\underline{B}) \rightarrow \underline{Proj}$ (and $CSP(\underline{B})$ is NP-complete), or one of the following statements holds (and $CSP(\underline{B}) \in P$)

- (1) *B is preserved by a constant operation.*
- (2) B is preserved by a minimum or maximum, $CSP(\underline{B})$ can be solved by AC_B .
- (3) \underline{B} is preserved by the majority, $CSP(\underline{B})$ can be solved by PC_B
- (4) \underline{B} is preserved by the minority, CSP(\underline{B}) can be solved by Gaussian elimination.

Lemma. A relation $R \subseteq \{0,1\}^k$ is preserved by a minority iff R is the space of solutions of a system of linear equations over GF_2 .

More generally:

Proposition (linear algebra). T.f.a.e.:

- R is (affine) linear subspace of V^k
- R is a space of solutions of (inhomogeneous) homogeneous system of linear equations
- R is invariant under (affine) linear combinations $\alpha_1 x_1 + ... + \alpha_n x_n$ (s.t. $\alpha_1 + ... + \alpha_n = 1$)

Theorem (Bulatov & Dalman). Let \underline{B} be a finite structure of a finite signature with Maltsev polymorphisms. Then $CSP(B) \in P$.

Remark:

- Generalizes linear systems over finite fields being in P, but not the solving algorithm
- The new algorithm for solving the CSP's (next section) also works for the so called *edge polymorphisms*
- **Examples.** Let G be a group, $m(x, y, z) := x \cdot y^{-1} \cdot z$. If $G = \mathbb{Z}_p$, then the relations preserved by m are precisely the affine subspaces of GF_p^k . In this case we can solve CSP(G) with Gaussian elimination. We can extend this to abelian groups (m becomes minority), there are however no known extensions for general finite groups (for example S_3).
- Let m be the minority on $\{0,1,2\}$ s.t. m(x,y,z)=2 whenever $|\{x,y,z\}|=3$. Then $(\{0,1,2\},m)$ has a congruence with equivalence classes $\{2\},\{0,1\}$,

$$\{(2,...,2)\} \cup \{(x_1,...,x_n) \in \{0,1\} \mid x_1 + ... + x_n \equiv_2 1\} \in Inv(m).$$

4 FUNCTIONS AND RELATIONS

• Let m be the minority on $\{0,1,2\}$ s.t. m(x,y,z)=x whenever $|\{x,y,z\}|=3$. There are no non-trivial congruences preserved by m. We have $R_f \in \operatorname{Inv}(m)$, where $R_f = \{(x,\pi(x)) \mid x \in \{0,1,2\}\}$ and $f \in S_3$. Moreover: $R \in \operatorname{Inv}(m)$, where R is maximal binary relation s.t. $|\pi_1^2(R)| \le 2$, $|\pi_2^2(R)| \le 2$.

4.3 compact representations of relations

Definition. Let $R \subseteq A^n$.
